✓ Ex: Modrek B, Resch A, Grasso C, Lee C. Genome-wide detection of alternative splicing in expressed sequences of human genes. Nucleic Acids Res 2001 Jul 1;29(13):2850-9 :

We have identified **6201 alternative splice relationships in human** genes, through a genome-wide analysis of expressed sequence tags (ESTs). Starting with approximately 2.1 million human mRNA and EST sequences, we mapped expressed sequences onto the draft human genome sequence and only accepted splices that obeyed the standard splice site consensus. A large fraction (47%) of these were observed multiple times, indicating that they comprise a substantial fraction of the mRNA species. **The vast majority of the detected alternative forms appear to be novel, and produce highly specific, biologically meaningful control of function in both known and novel human genes,** e.g. specific removal of the lysosomal targeting signal from HLA-DM beta chain, replacement of the C-terminal transmembrane domain and cytoplasmic tail in an FC receptor beta chain homolog with a different transmembrane domain and cytoplasmic tail, likely modulating its signal transduction activity. **Our data indicate that a large proportion of human genes, probably 42% or more, are alternatively spliced,** but that this appears to be observed mainly in certain types of molecules (e.g. cell surface receptors) and systemic functions, particularly the immune system and nervous system. These results provide a comprehensive dataset for understanding the role of alternative splicing in the human genome, accessible at http://www.bioinformatics.ucla.edu/HASDB.

Analysis of PAS-flanking regions
Most Frequent Hexamers

The AAUAAA and AUUAAA hexamers are the most frequently found.

26.8% of the 3" fragments do not contain a usual polyadenylation signal.

Ten variant motifs are found accounting for 14.9% of the putative mRNA 3' ends

As expected from experimentally validated signals, AAUAAA and AUUAAA hexamers are clearly clustered around −15/−16 nt upstream of the putative poly(A) site.

Variant hexamers are also clustered around positions −15/−20.

Most significant hexamers in 3' fragments

Hexamer	Observed (expected)[a]	% sites	P[b]	Position ave +\− SD	Location[c]

A large-scale analysis of mRNA polyadenylation of human and mouse genes

Bin Tian*, Jun Hu, Haibo Zhang[1] and Carol S. Lutz

Department of Biochemistry and Molecular Biology, New Jersey Medical School, UMDNJ, Newark, NJ 07101, USA and [1]Center for Computational Biology and Bioengineering, New Jersey Institute of Technology, Newark, NJ 07102, USA

-> 54% human, 32% mouse (accept multiple sites for 1 signal, but refseq UTR only)

How many polyadenylated genes between Ensembl annotated genes?

Low estimate (false positive PAS are 2.4 times more frequent in intergenic):

3370 genes

High estimate (false positive PAS are 1.2 times more frequent in intergenic):

6730 genes

What is the actual reach of 3'UTRs?

Textbook « Human Molecular Genetics 2 » (1999):

★ 3′ UTR Average of about 0.6 kb (see Zhang, 1998) but this is likely to be an underestimate because of underreporting of genes with long 3′ UTRs

Untranslated Regions of mRNA (Mignone et al. 2003) :

	5' UTR				3' UTR			
	Number of sequences	Average length	Maximum length	Minimum length	Number of sequences	Average length	Maximum length	Minimum length
Humans	1,203	210.2	2,803	18	1,247	1,027.7	8,555	21
Other mammals	142	141.3	936	20	148	441.1	3,324	37

A large-scale analysis of mRNA polyadenylation of human and mouse genes

Bin Tian*, Jun Hu, Haibo Zhang [1] and Carol S. Lutz

★ All rely on EST sampling, but:
- Require <u>alignment on refseq gene/fl cdDNA</u> or <u>overlapping ESTs</u>
- Cannot assess all long range PAS

How can you make sure a PAS pertains to the nearest 5' gene ?

In the absence of overlapping ESTs: danger!

★ There could be another gene in the interval

★ PAS could be just noise (29000 PAS at >10kb from any Ensembl gene)

=> We need a <u>gauge</u> to evaluate PAS reality

Gauge: signal usage

★ Noisy PAS are expected to use random polyA signals
★ Independent of EST coverage
★ True PAS appear dominant up to 15kb!

Direct UTR counts
UTR length

Integrate curve up to 15kb

All UTRs (mouse)

★ Mean UTR size: 2100nt (1850)

★ Median: 1100nt (1000)

3'-most PAS (longest transcript)

★ Mean UTR size: 2450nt (1900)

★ Median: 1400nt (1100)

★ 10% of genes have 3'UTR longer than 6400nt

Selected PAS or transcriptional leakage?

- 3' UTR sizes from orthologues (Ensembl)….

UTR size in human | UTR size in mouse

```
                 UTR size in mouse

        -------------------------

bp        <100  <1k   <10k

        -------------------------

<100      286   195   99

<1k       256   4396  1334

<10k      131   1527  3004

        -------------------------
```

- Chi2 Probability ~ 0!
- Long UTR in human => long UTR in mouse

Much to discover in 3'UTR

★ Independent measures converge towards significant numbers of UTRs up to 10-15kb with mean size = 2.4kb.

★ Ensembl mean 3'UTR size (longest non-zero UTR of each gene): 1.2kb

★ Then each Ensembl gene may lack in average 50% of its actual 3' UTR

★ This doubles total search space for regulatory motifs, miRNA targets etc.

Le Tiling Array
Dark matter in the genome: evidence of widespread transcription detected by microarray tiling experiments

Jason M. Johnson[1], Stephen Edwards[1], Daniel Shoemaker[2] and Eric E. Schadt[1]

[1]Rosetta Inpharmatics LLC*, 401 Terry Avenue North, Seattle, WA 98109, USA
[2]GHC Technologies, 505 Coast Boulevard South, Suite 309, La Jolla, CA 92037, USA

★ Rosetta: technologie de spottage d'oligonuléotides par jet d'encre (inkjet)

Box 1. Tiling microarray experiments

Tiling microarrays are designed to assay transcription at regular intervals of the genome using regularly spaced probes (horizontal red lines) that can be overlapping (Figure I) or separated. The distance between the centers of successive probes is the 'step' size and probes can be selected to be complementary to one strand (as shown) or both strands. Probes can be synthesized directly onto or spotted onto glass slides, and can be synthesized oligonucleotides or PCR products. They are hybridized with fluorescently labeled cRNA or cDNA prepared from cell samples. Regions of greater fluorescent intensity (green peaks in lower panel) can reveal transcription within a large genomic region. In addition, the correlation of probe intensities in several different tissues (co-expression analysis) can be used to identify probes that are detecting exons of the same transcript. The lower panel shows the extent of a hypothetical transcript within the genome. The middle panel is a schematic, magnified view of the hybridization of a genomic region containing an exon.

TRENDS in Genetics
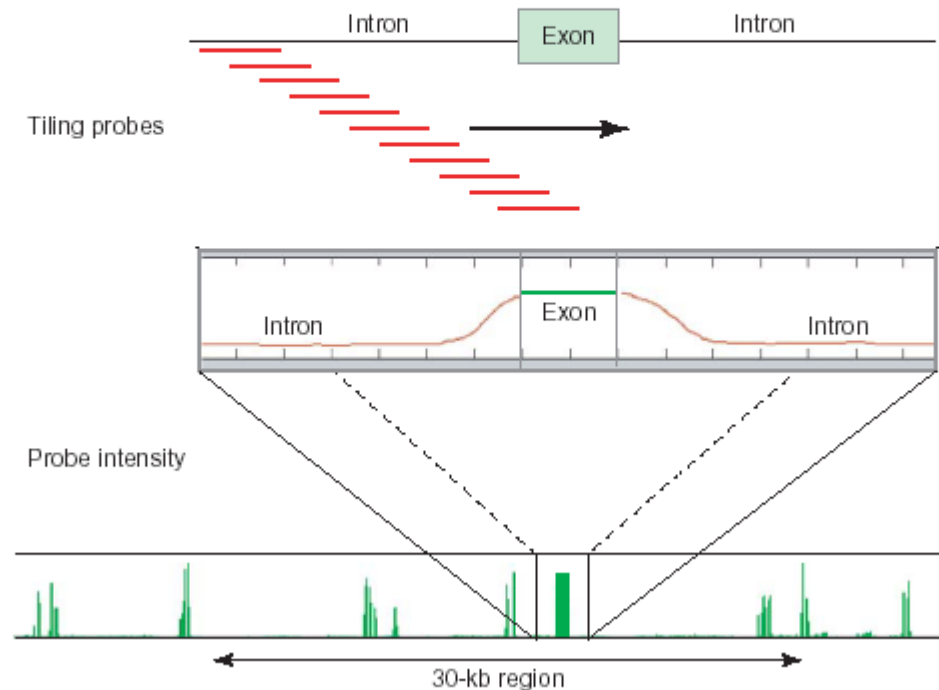

Figure 1. Microarray intensity profile for human thymus poly(A)⁺ cDNA profiled on a 60mer ink-jet tiling array representing the genomic locus of the Ewing sarcoma breakpoint region 1 gene (*EWSR1*) in 30-nt steps, with probe index as the x-axis. No probes are shown for repeat-masked regions. The tiling data for this locus are shown in relation to the exon positions (below the plot) of three EWSR1 cDNAs (Genbank accession numbers: NM_013986, NM_005243.1 and AK026270). The 5′-most exon lies in a repeat-masked region and is not shown. A few peaks with the highest intensity have been truncated in Figures 1–3.

★ Gène bien caractérisé: confirmation des exons « refseq » et apparition de nouvelles régions transcrites (ici correspondant à un cDNA déjà observé)

The first example shows expression activity for a well-characterized gene, Ewing sarcoma breakpoint region 1 (*EWSR1*; Figure 1). The tiling data clearly detect exons corresponding to the RefSeq transcript of this gene but there also appears to be additional signal in at least one intron. The transcript represented by the cDNA sequence AK026270, shown in Figure 1, might correspond to a portion of this activity (as might others such as AL833489 and BX648769, not shown). In this case, the unexplained transcription suggests there are alternatively spliced isoforms or other uncharacterized RNAs transcribed from this locus.
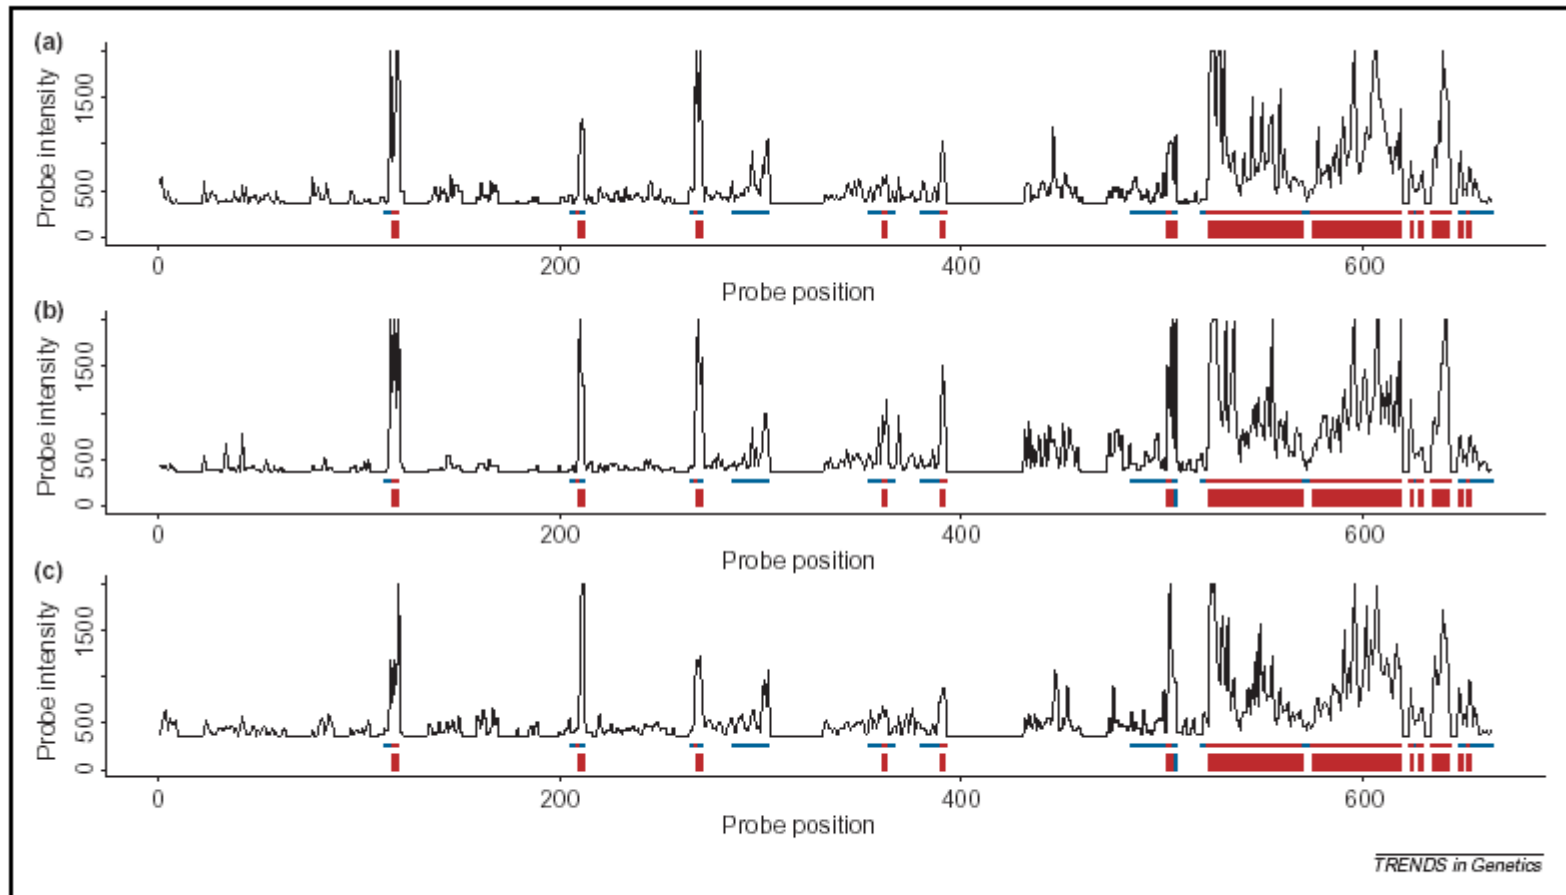

Figure 2. Microarray tiling confirmation of a predicted gene. Microarray tiling probe intensities for a region of human chromosome 20 that contains an *ab initio* gene prediction (made by the program GENSCAN [48]). Predicted exons for this gene are shown with blue lines. The transcription detected by microarrays has been grouped into a single transcriptional unit (dark red) by the correlated behavior of these probes across different human samples [11]. The conditions displayed are (a) thalamus, (b) testes and (c) uterus.

★ Gène prédit: confirmation ou non des exons prédit par Genscan ou autre.
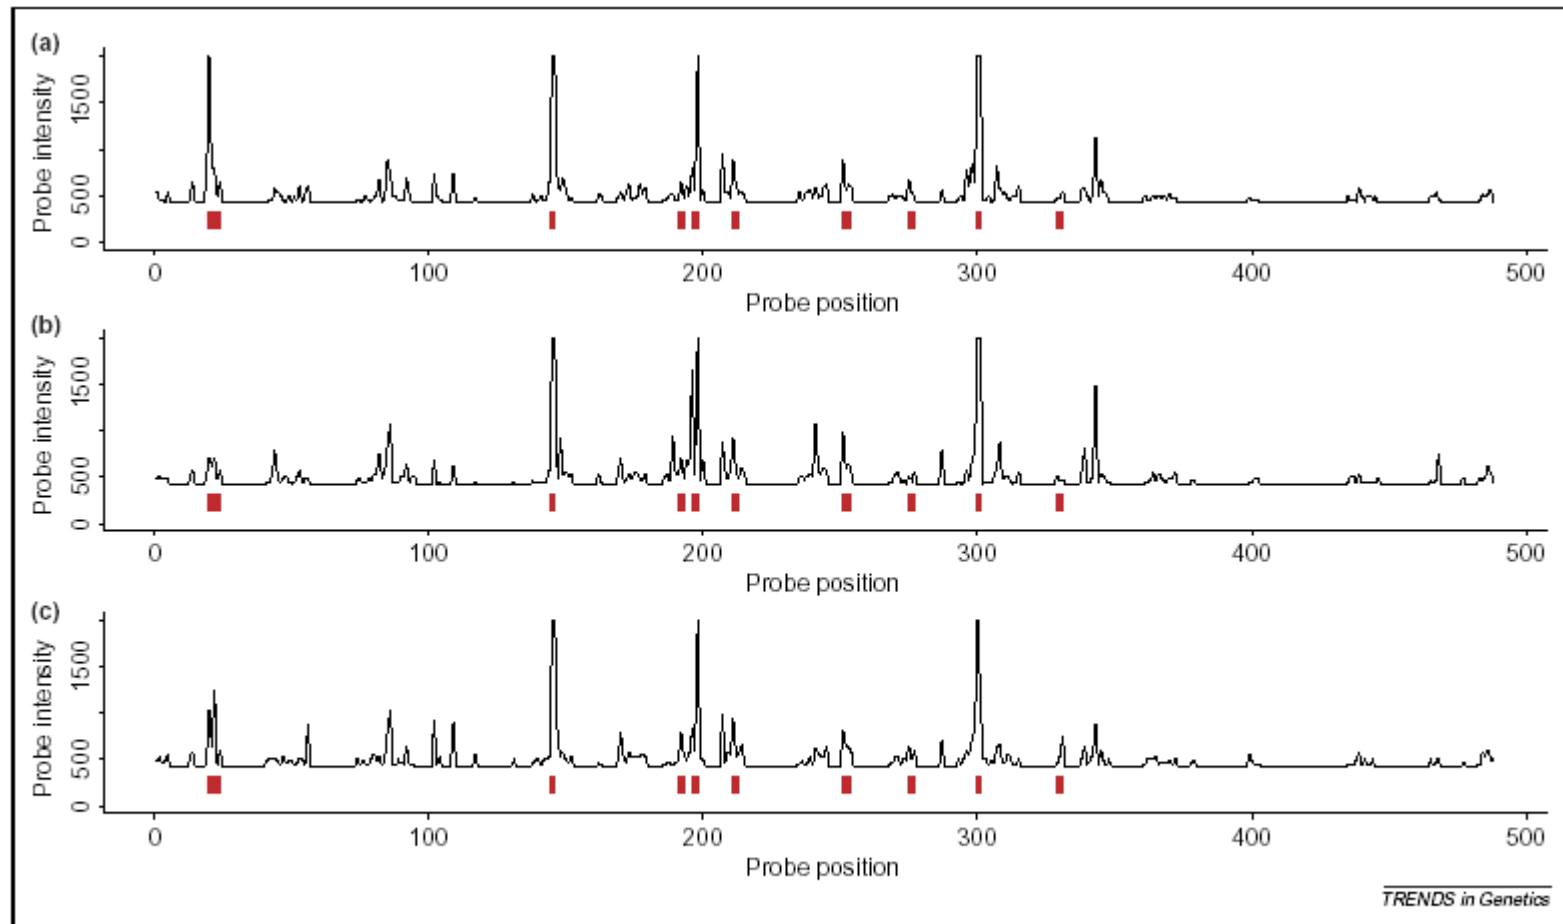

Figure 3. Tiling intensity profile for poly(A)+ RNA samples from **(a)** thalamus, **(b)** testes and **(c)** uterus from an intergenic region of human chromosome 20 that contains no mapped ESTs or computational gene predictions. Dark red bars indicate transcription activity that has been grouped into a single transcriptional unit given the relative activity of these probes with respect to one another across different samples as described in Schadt *et al.* [11].

★ Apparition de nouveaux gènes dans régions intergéniques sans EST ni prédiction bioinformatique.

Que trouve-t-on?

- ★ **Nouveaux gènes codants**
  - >2000 transcrits avec ORF non existant dans Ensembl
- ★ **Nouveaux gènes non-codants**
  - >10000 transcrits
- ★ **Transcrits antisens**
  - >5000 gènes ont transcription antisens
- ★ **Isoformes de gènes connus**
  - Au moins 40% à 60% des gènes selon auteurs
  - Comprend également extensions (parfaois très longues) en 3'
- ★ **Artefacts**
  - biologiques: « bruit » transcriptionnel
  - expérimentaux: hybridation non-spécifique, contamination génomique…

Bailey,[1] Madhavan Ganesh,[1] Srinka Ghosh,[1] Ian Bell,[1] Daniela S. Gerhard,[2] Thomas R. Gingeras[1]†

Science, 2005

★ Technologie: Affymetrix

★ 25-mères espacés de 5bp

★ polyA+ et polyA-

★ Noyau et cytoplasme

★ 8 lignées cellulaires différentes

Etat de polyadenylation

★ Parmi tous les transcrits observés:

- 19% polyA+
- 44% polyA-
- 37% polyA+ et polyA-

- Donc la moitié du transcriptome humain est polyA-

- Important, car les transcrits qu'on regardait jusqu'à présent n'étaient que les polyA+!

★ La plupart des polyA- nucléaires sont introniques (normal)
★ Mais >50% des transcrits cytoplasmiques sont polyA-

Position des transcrits

★ 60% des loci exprimés présentent des évidences de transcription sur 2 brins

★ Beaucoup de transcription dans l'intergénique:

- 50% des polyA- cytoplasmiques et 25% des polyA- nucléaires sont intergéniques

- 41% des polyA+ nucléaires sont intergéniques

The Transcriptional Landscape of the Mammalian Genome

The FANTOM Consortium* and RIKEN Genome Exploration Research Group and Genome Science Group (Genome Network Project Core Group)*
Science, 2005

Sequence conservation of mouse promoters vs. human

Transcrits et Unités de Transcription

★ TU: Transcription Unit. mRNAs sharing at least 1 nt and with same location and orientation

Table 2. Transcript grouping and classification. The extent of splice variation was calculated by excluding T-cell receptor and immunoglobulin genes from the transcripts. The remaining 144,351 transcripts were grouped in 43,539 TUs, of which 18,627 (42.8%) consist of single-exon transcripts, 8110 (18.6%) contain a single multiexon transcript, and the remaining 16,802 TUs (38.6%) contain at least two spliced transcripts. Among these TUs, 5862 (34.9%) show no evidence of splice variation, whereas 10,940 (65.1%) contain multiple splice forms.

	Total	Average per TU cluster
Total number of transcripts	158,807	7.59
RIKEN full-length	102,801	
Public (non-RIKEN) mRNAs	56,006	
GFs	25,027	1.20
Framework clusters	31,992	1.53
TUs	44,147	2.11
With proteins	20,929	1.00
Without proteins	23,218	1.11

Conclusion projet « FANTOM3 »

★ 32000 transcrits non-codants

★ 16000 nouveaux transcripts codants

★ 5000 nouvelles protéines

★ La majorité du génome est transcrit sur les deux brins

★ La grande diversité des transcrits dans chaque TU soulève le problème de la précision des puces ADN conventionnelles, dans lesquelles chaque sonde hybride différents transcrits

Les besoins actuels

★ Intégration initiation+épissage+transcription

★ Etude fonctionnelle (domaines, etc.)

★ Conservation

★ Validation expérimentale

★ Tissu-spécificité
